Advanced R programming: practical 1

Dr Colin Gillespie

November 27, 2014

1 Rprofile and Renviron

1. Create an `.Rprofile` file. Add the line

```r
if(interactive()) {
    suppressWarnings(require(colorout, quietly=TRUE))
    message("Successfully loaded .Rprofile at ", date(), "\n")
}
```

   to the file and restart R. Does the welcome message appear?

   An easy way of creating the file is to use the R function `file.create`, so

```r
file.exists("~/.Rprofile")
file.create("~/.Rprofile")
```

2. Try adding my suggestions to your `.Rprofile`, e.g.

```r
options(prompt="R> ", digits=4,
        show.signif.stars=FALSE)
```

   and setting the CRAN mirror:

```r
r = getOption("repos")
r["CRAN"] = "http://cran.rstudio.com/"
options(repos = r)
rm(r)
```

3. Try adding a few functions to your `.Rprofile`. Use the hidden environment trick. Also take a look at this stackoverflow question

   `http://goo.gl/TLFLQR`

   for ideas.

4. Create an `.Renviron` file and add the path to your packages.

2 Argument matching

R allows a variety of ways to match function arguments.[1] We didn't cover argument matching in the lecture, so let's try and figure out the rules from the examples below. First we'll create a little function to help

[1] For example, by position, by complete name, or by partial name.

```r
arg_explore = function(arg1, rg2, rg3)
    paste("a1, a2, a3 = ", arg1, rg2, rg3)
```

Next we'll create a few examples. Try and predict what's going to happen before calling the functions

One of these examples will raise an error - why?

```r
arg_explore(1, 2, 3)
arg_explore(2, 3, arg1 = 1)
arg_explore(2, 3, a = 1)
arg_explore(1, 3, rg = 1)
```

Can you write down a set of rules that R uses when matching arguments?

Following on from the above example, can you predict what will happen with

```r
plot(type="l", 1:10, 11:20)
```

and

```r
rnorm(mean=4, 4, n=5)
```

3   Functions as first class objects

Suppose we have a function that performs a statistical analysis

```r
## Use regression as an example
stat_ana = function(x, y) {
  lm(y ~ x)
}
```

However, we want to alter the input data set using different transformations[2]. In particular, we want the ability to pass arbitrary transformation functions to stat_ana.

[2] For example, the log transformation.

- Add an argument trans to the stat_ana function. This argument should have a default value of NULL.

- Using is.function to test whether a function has been passed to trans, transform the vectors x and y when appropriate. For example,

```r
stat_ana(x, y, trans=log)
```

  would take log's of x and y.

- Allow the trans argument to take character arguments in additional to function arguments. For example, if we used trans = 'normalise', then we would normalise the data[3].

[3] Subtract the mean and divide by the standard deviation.

4   Variable scope

Scoping can get tricky. **Before** running the example code below, predict what is going to happen

1. A simple one to get started

```
f = function(x) return(x + 1)
f(10)
```

2. A bit more tricky

```
f = function(x) {
  f = function(x) {
    x + 1
  }
  x = x + 1
  return(f(x))
}
f(10)
```

3. More complex

```
f = function(x) {
  f = function(x) {
    f = function(x) {
      x + 1
    }
    x = x + 1
    return(f(x))
  }
  x = x + 1
  return(f(x))
}
f(10)
```

4.
```
f = function(x) {
  f = function(x) {
    x = 100
    f = function(x) {
      x + 1
    }
    x = x + 1
    return(f(x))
  }
  x = x + 1
  return(f(x))
}
f(10)
```

5   Function closures

Following the examples in the notes, where we created a function closure for the normal and uniform distributions. Create a similar closure for

- the Poisson distribution,[4]
- and the Geometric distribution.[5]

6   Mutable states

In chapter 2, we created a random number generator where the `state`, was stored between function calls.

- Reproduce the `randu` generator from the notes and make sure that it works as advertised.

- When we initialise the random number generator, the very first state is called the `seed`. Store this variable and create a new function called `get_seed` that will return the initial seed, i.e.

```r
r = randu(10)
r$r()

## [1] 0.0003051898

r$get_state()

## [1] 655390

r$get_seed()

## [1] 10
```

- Create a variable that stores the number of times the generator has been called. You should be able to access this variable with the function `get_num_calls`

```r
r = randu(10)
r$get_num_calls()

## [1] 0

r$r()

## [1] 0.0003051898

r$r()

## [1] 0.001831097

r$get_num_calls()

## [1] 2
```

Solutions

Solutions are contained within the course package

```r
library("nclRadvanced")
vignette("solutions1", package="nclRadvanced")
```
