

## Introduction to R: practical 2

Dr Colin Gillespie

Often when we commence an analysis we want to partition the data in different ways. For example, selecting data points greater than a particular value. In this practical we will investigate how this is done using R's logical operators.

### Question difficulty

Some of the questions below are straight forward, others are bit more tricky.

- The last sub-questions of Q1 and Q2 are hard.

Before starting the practical, run the following command:

```
library("nclRcourses")
```

### Question 1

Run the following R code

```
x1 = GetNumericVector()
```

1. What is length of x1?

```
length(x1)

## [1] 52655
```

2. What is the 55<sup>th</sup> element of x1?

```
x1[55]

## [1] 38.3
```

3. What is the final element of x1?

```
x1[length(x1)]

## [1] -3.3

tail(x1, 1)

## [1] -3.3
```

4. What is the mean value of x1?

```
mean(x1)

## [1] -1.334
```

5. What is the smallest value of  $x_1$ ?

```
min(x1)

## [1] -87.3
```

6. How many values are greater than the first quartile but less than the median?

```
q1 = quantile(x1)[2]
med = median(x1)
length(x1[x1 > q1 & x1 < med])

## [1] 13048

## Or
sum(x1 > q1 & x1 < med)

## [1] 13048
```

7. How many values are greater than  $\bar{x}_1 + 2sd(x_1)$ , where  $sd$  is the sample standard deviation?

$\bar{x}_1$  is the mean value and  $sd(x_1)$  is the standard deviation of  $x_1$ .

```
m = mean(x1)
s = sd(x1)
sum(x1 > (m + 2 * s))

## [1] 1254
```

8. **Tricky:** What is the 50<sup>th</sup> smallest value in  $x_1$ ?

```
sort(x1)[50]

## [1] -63.7
```

### Question 2

Run the following R code

```
y = GetDataFrame()
```

The data frame  $y$  is a subset of the yeast data we use in the lectures.

1. How many rows does  $y$  have?

```
dim(y)[1]

## [1] 14937
```

2. How many columns does y have?

```
dim(y)[2]

## [1] 5
```

3. What are the different cell types in this data set?

```
unique(y$type)

## [1] mutant wild
## Levels: mutant wild
```

4. How many measurements have been made on mutant cells?

```
sum(y$type == "mutant")

## [1] 7468
```

5. How many of probes have expression levels less than 5?

```
sum(y$value < 5)

## [1] 456
```

6. How many measurements have been made at time point 0?

```
sum(y$tps == 0)

## [1] 2985
```

7. How many mutant probes were measured at time point 0?

```
sum(y$tps == 0 & y$type == "mutant")

## [1] 1493
```

### Question 3

Run the following R code

```
x2 = GetCharacterVector()
```

In the following questions, the function `table` is quite useful, especially when combined with `sum`, `sort`, etc.

1. How many times does “A” appear in `x2`?

```
length(x2[x2 == "A"])

## [1] 2095

## Or
sum(x2 == "A")

## [1] 2095
```

2. Which letter appears the most? If more than one letter appears, just give the first letter (if the letters were sorted in alphabetical order).

```
sort(table(x2), decreasing = TRUE)[1]

##      W
## 2108
```

3. **Very tricky:** How many pairs of letters are there in `x2`.<sup>1</sup>

```
l = length(x2)
x2_a = x2[1:(l - 1)]
x2_b = x2[2:l]
sum(x2_a == x2_b)

## [1] 2074
```

<sup>1</sup> For example, in AABCCC we would have 3 pairs: AA, CC and CC.
